

Estella Jangaon  
16023 Sandy Ring Ct  
Cypress, TX 77429

Dear Estella Jangaon,

Thank you for participating in the Health & Wellness Screening Voucher Service sponsored by your worksite. Enclosed are your results for your review. Included with the results are normative ranges for each biometric value.

**Lab Result Information:**

**Date of Test:** 10/18/2016

**Name:** Estella Jangaon

**DOB:** 04/09/1963

| Test Name          | Reference Interval | Your Results |
|--------------------|--------------------|--------------|
| Glucose, Serum     | 65-99 mg/dl        | 145          |
| Cholesterol, Total | 100-199 mg/dl      | 164          |
| HDL                | 40-59 (or higher)  | 39           |
| LDL                | 0-99 mg/dl         | 99           |
| Triglycerides      | 0-149 mg/dl        | 130          |
| A1C                | 4.8-5.6 %          | 6.2          |

The data derived from these tests are to be considered preliminary only and does not necessarily rule out nor confirm a diagnosis of illness or disease. Results of any health screening should be discussed with your personal physician to determine if any additional assessments are needed.

Healthfully yours,

The Interactive Health Team

## Explanation of Blood Test Results

This information is provided to help you understand your blood test results. Values which are outside reference ranges may indicate possible problems needing medical evaluation, may show that you ate before your blood was drawn or may mean there was difficulty in processing your blood. **CONSULT YOUR PERSONAL PHYSICIAN WITH ANY QUESTIONS AND MAKE AN APPOINTMENT FOR FUTURE EVALUATION IF YOUR DOCTOR INDICATES THAT THIS IS NECESSARY.** For additional questions, please call Interactive Health at 410-363-4948.

It is not possible to diagnose or treat any disease or problems with this blood test alone. It can help you learn more about your body and detect potential problems in early stages when treatment or changes in personal habits can be most effective.

**GLUCOSE:** This is a measure of blood sugar levels. This nutrient is used by the brain and other vital organs as an energy source. High levels may be associated with eating before the test or diabetes.

**CHOLESTEROL:** This is one of the major coronary risk factors. Evaluated levels in the blood are associated with the buildup of fatty deposits inside the blood vessels, especially those which supply blood to the heart and brain. Cholesterol levels can increase due to a dietary intake of fatty foods, eggs, liver and other organ meats, some shell fish and lack of aerobic exercise. Levels may decrease through regular exercise patterns and diet modification.

**HDL CHOLESTEROL:** This is one of the several fats which make up your total cholesterol level. HDL is referred to as the "good" cholesterol. It seems to transport fatty deposits away from the arterial walls to the liver. It has been shown the HIGHER the PERCENT of HDL CHOLESTEROL, the lower the risk of developing heart disease.

**CHOLESTEROL/HDL RATIO:** The ratio is obtained by dividing the HDL cholesterol level into the total cholesterol. The goal is to keep the ratio at or below 5.0; the optimum ratio is about 3.5.

**LDL CHOLESTEROL:** This is considered a "bad" cholesterol, because elevated levels of LDL cholesterol are associated with an increased risk of coronary heart disease. Low-density lipoprotein deposits cholesterol on the artery walls, causing the formation of a hard, thick substance called cholesterol plaque. Over time, cholesterol plaque causes thickening of the artery walls and narrowing of the arteries, a process called atherosclerosis.

**TRIGLYCERIDES:** These are also fatty acids found in the blood which contribute to fatty deposits on arterial walls.

**A1C:** This measures your average blood glucose control over the past 2 to 3 months. The higher the percentage reported the higher a person's blood glucose levels have been.

**Cotinine:** Measuring cotinine, the primary metabolite of nicotine, is currently the best method to distinguish between those who use tobacco products and those who do not. The level of cotinine in the blood is proportionate to the amount of exposure to tobacco, including secondary (passive) smoke. A positive test results indicates that the level of cotinine detected can be contributed to tobacco usage. A negative test result indicates that cotinine is not present or is at a minimal level that does not imply tobacco usage.
